Adult female annual cycle

a Short trip: three discrete strategies

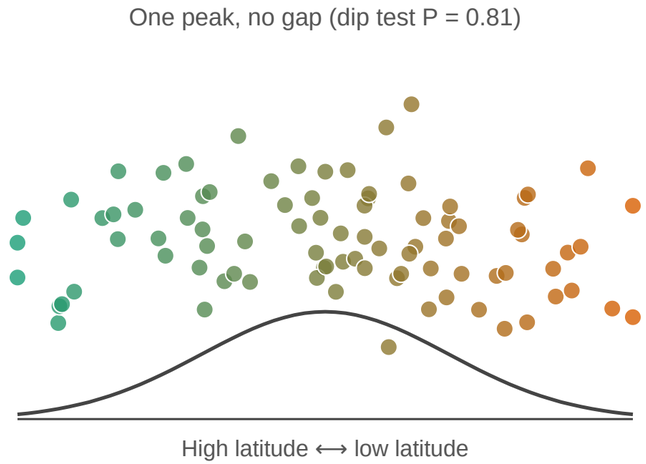

Robust to analytical choices; stable groups (Jaccard 0.85–0.99)

California Current: coastal, benthic, shorter trips, faster mass gain

Offshore strategies: separate areas, same isotopic niche ($\Delta\delta^{15}N$ 0.40 ‰, negligible)

b Long trip: a continuum

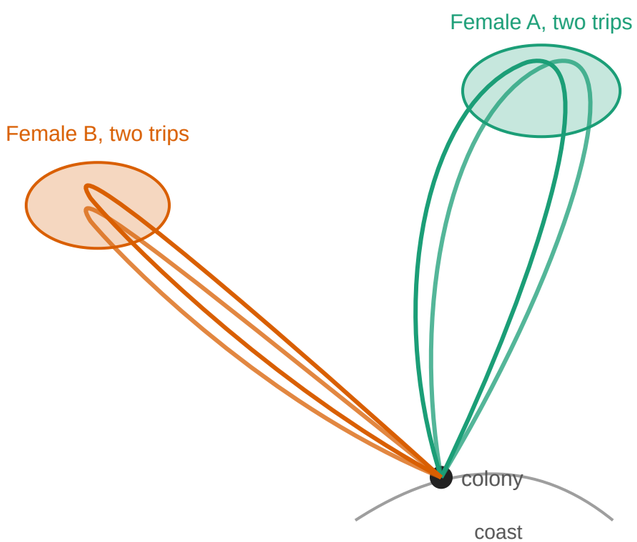

No discrete groups; no coastal strategy

Isotopes follow each female's position on the gradient, not group (ΔAICc ≈ 30–38)

More California Current use → higher $\delta^{13}C$, $\delta^{15}N$

c Females: consistent in where, not how

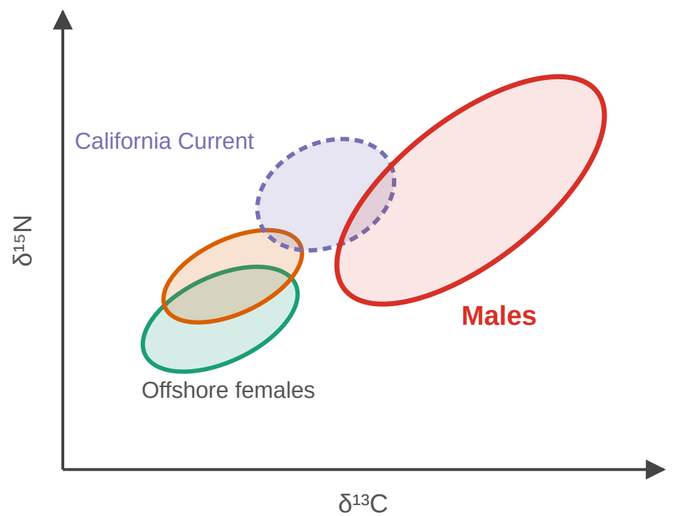

Same strategy in 23 of 27 trip pairs; changes only between trip types

Return to own area (overlap 0.81 vs 0.46 same-strategy females)

Isotopes repeatable (R ≈ 0.76); diving effort not (R = 0.26)

d Males: one broad, enriched niche

No discrete groups; one isotopic gradient

Niche 2–4× wider than any female group

Most females fall in the male niche; few males in female niches

Schematic; not to scale
